

The program filesort needs two arguments to be given at initial program call.

The first argument right after ./fileSort needs to be either “-i” or “-q”. -i is if insertion sort is desired and -q is if quicksort is desired to be used on the text file. One must be chosen.

The last argument is the location of a txt file to be sorted. The contents of the file should have either all numbers separated by commas, or all lowercase letters separated by commas.

The sorted list will then be printed in standard output one line at a time, removing any commas and spaces, tabs, newlines, and other breaks in the token sequences.
